

Login Module

Create a Servlet/JSP application with a facility to (1)Login to the application (2) Register a new user and (3) Change password for an existing user

A HTML page with a facility to Login and two hyperlinks for New User and change Password need to be created

- When user enters user name and password and clicks on submit button, if he is a valid user he should be taken to the home page. If the credentials are invalid it must redisplay the form again with an appropriate message.
- When user clicks '**new user**' link, a form with user name, password and retype password text fields gets displayed along with *add* button. When user clicks the add button, validate the password and retyped password at the client side and submit this information to Login servlet that stores the user name and password in the database and redirects him to the Login Page
- When user selects '**change password**' link, he should be asked to enter his user name, old password, new password and retype the new password.
- The application should check if the username and his old password is right with the database and that the new password and the retyped password are same.
If all the above conditions are met, then the corresponding user's password should be updated in the database
